USING GENETIC ALGORITHM TO OPTIMISE MACHINE LAYOUT PROBLEM

Abstract: In this paper, it is presented problem of machine layout optimization. The importance of resolving the problem is large for manufacturers, who want to save production time and cost. Poor layout gives longer traveling distance from one machine to another and bigger cost in handling the material for production. Time saving and cost reduction are achieved by reducing the travel distance of people, especially material and informations. The paper deals with genetic algorithm whose objective is to find the appropriate placement of the machines in workspace.

Keywords: genetic algorithm, machine layout, travel distance

1. INTRODUCTION

One of the biggest problems in the design of workspace manufacturers of heavy industry is the layout of machines. Importance of layout machines is manifested through cost of the material handle, time and material flow. Material handling costs contribute an estimated 15 to 70 % of total operation expenses and can be reduced by approximately 10 to 30% if an efficient layout is employed [4]. In that way machine layout affects on manufacturers productivity and efficiency.

How the machines will be placed depends on the type of manufacturing industry. There are many types of layouts. Extreme layouts are layout by product and layout by function. Layout by product is a layout with high volumes of products, but with low variety of products, on the other hand layout by function is a layout with high variety of products and low volumes of products. Type of layout that stands between these types is cellular layout. For heavy industry, whose layout is considered in this paper it is used layout by product.

A product layout arranges activities in a line according to the sequence of

operations for a particular product or service. This would be an assembly line, such as a ship's winch line. This kind of line is efficient, but it has its imperfections. So the finding of optimal path between machines would reduce these imperfections.

Machines layout path is combinatorial optimization problem that attempts to find an optimal path through layout from a finite set of paths. An optimal tour is one which distance is minimized.

A large variety of optimisation solutions for layout are found in literature. Such as heuristic methods like genetic algorithm and ant colony optimisation algorithm (ACO), optimisation could be done by using quadratic assignment problem (QAP) formulation.

An ACO algorithm is an artificial intelligence technique based on the pheromone-laying behavior of ants; it can be used to find solutions to exceedingly complex problems that seek the optimal path through a graph. [2]

QAP formulation is a fundamental combinatorial optimization in the branch of optimization or operation research in mathematics, from the category of the
