Although the food industry is moderately energy-intensive, it belongs to industries with significant CO₂ emissions due to its scope, potential growth, and energy use. Therefore, it has been identified as one of the crucial factors in the industrial sectors' overall decarbonisation process. The margarine industry and processing of vegetable oils and fats are a fast-growing segment of this industrial sector, characterized by energy-intensive processes, such as cooling, water vapour preparation, and pasteurization. Energy supply (electricity and heat) is one of the essential parts of the technological process that can significantly contribute to the decarbonisation of the entire production process by applying energy-efficient technologies and renewable energy sources. The decarbonisation program can assist the margarine and vegetable oils and fats processing industries in becoming more competitive in the market while reducing their carbon footprint. Along with efforts to reduce CO₂ emissions, energy consumption costs are also decreasing. Furthermore, decarbonisation will result in lower future CO₂ expenses.

First of all, the global paradigm of industrial decarbonisation implies the electrification of processes, which assumes that facilities will be supplied with more renewable electricity. However, the ability to use renewable electricity is primarily determined by the characteristics of the power system to which the facility is connected. Cogeneration, on the other hand, is one of the most efficient technologies for generating electricity and heat. As a result, the paper proposes a methodology for determining the optimal solution for cogeneration (CHP) and rooftop photovoltaics (PV) for minimising CO₂ emissions. The methodology is based on material and energy flow analysis in the manufacturing process and electricity and heat consumption/load profiles. Based on the created consumption/load profiles, technical limitations, and legal regulations, the possibility of installing rooftop PV panels and implementing suitable CHP technology is considered. The proposed methodology is applied and tested on a margarine production facility. The integrated use of CHP and rooftop PV panels could reduce CO₂ emissions by up to 71% if the PV panels were installed on the fully accessible roof surface and up to 55.7% if 150 kW were installed in accordance with the new national regulation.

Key words: *food industry, photovoltaic (PV), cogeneration (CHP)*
